Emergency Medicine Cape Town

2015 research summary
Emergency Medicine research outputs

Relevant findings for the year 2015

This document summarises the most relevant research content from the academic Divisions of Emergency Medicine. This document was compiled from both research outputs through dissertation and publication (in some instances both). Where a publication resulted from a dissertation, the publication was referenced and not the dissertation. Unpublished papers and material have not been included in this report.

Reading this document

Findings are arranged alphabetically by the author’s last name. Findings of particular interest are highlighted in the table of contents and clearly marked in the text. Original dissertations from the University of Cape Town are available on OpenUCT. Original dissertations from Stellenbosch University are available in the Tygerberg campus library. Publications are all available online.

1 Emergency Medicine Division Research Committee (EMDRC) research turnover and outputs

The EMDRC improved its turnover in 2015 from 2014 (Table 1). Submissions to the EMDRC increased by 113%, approved summaries increased by 160% and approved proposals doubled from 18 to 36. This will undoubtedly have an impact on research outputs for 2016 and beyond. The figures for 2015 have been the highest on record since the EMDRC was founded in 2011.

2 Research outputs: original research publications

There were 26 published original research papers. There were dissertations (part 3). Where a publication followed a dissertation, the summary is provided with the publication. Some findings from dissertations submitted in 2015 are scheduled for publication in 2016. These have not been included in this report and will be reported in the midyear report. In addition to these there were five opinion pieces (part 4), which included editorials and op-eds. Contributions to regular features and published conference proceedings are not included. A short summary is given of published papers and dissertations whilst only the references are listed for the opinion pieces. The research list is provided alphabetically by first letter of the first author’s surname.

2.1 Different teaching techniques appears equal in providing skill and knowledge of manual defibrillation skill in medical students

The study investigated the influence of three different instructional approaches (traditional, Peyton’s four-stage, and a modified five-step method) on the acquisition and retention of manual defibrillation skills. It was unable to determine which method would be best suited for simulation-based teaching in a resource-constrained environment; none of the three instructional approaches proved to be superior.

2.2 International Point of Care Ultrasound Curriculum

The International Federation for Emergency Medicine’s sub-committee of international experts in point of care ultrasound outlines a curriculum for training of specialists in emergency point of care ultrasound. This curriculum document represents the consensus of recommendations by this sub-
committee. The curriculum is designed to provide a framework for point of care ultrasound education in emergency medicine

2.3 Poor short-term outcomes regarding prehospital treatment for patients with symptomatic hypoglycaemia

A total of 110 patients treated pre-hospitally for hypoglycaemia were telephonically interviewed. It was found that 21 (19%) had subsequently died, 30 (34%) reactivated EMS within seven days of prehospital treatment, 48 (54%) had recurrent episodes within seven days of prehospital treatment and in 47 (53%) received no follow-up instructions. The current strategy of dealing with hypoglycaemia in the prehospital environment needs careful re-evaluation to improve the quality of management of this patient population.

2.4 The use of smartphone cameras in clinical practice

Whereas one smartphone camera ranked best more often, all three smartphones obtained results at least as good as those of the digital camera. Smartphone cameras can be a substitute for digital cameras for the purposes of medical tele-consultation.

2.5 Photograph-based diagnosis of burns in patients with dark-skin types

Size and depth of burns on patients with dark-skin types could be assessed at least as well using photographs as at bedside with 67.5% and 66.0% average accuracy rates. Case characteristics
significantly affected the accuracy for burn size, but medical specialty and country of practice seldom did in a statistically significant manner.

2.6 Blood cultures in a high HIV prevalent setting and the emergency centre

From: Boyles TH, Davis K, Crede T, Malan J, Mendelson M, Lesosky M. Blood cultures taken from patients attending emergency departments in South Africa are an important antibiotic stewardship tool, which directly influences patient management. BMC Infect Dis. 2015;15:410

Blood cultures taken from patients attending emergency departments in a high HIV prevalent city in South Africa are frequently positive and almost always influence patient management. At least 8 ml of blood should be inoculated into each bottle. Blood cultures should be taken from all patients attending ECs in South Africa suspected of having blood stream infection particularly if diabetic, with hypotension, tachycardia or if biliary sepsis is suspected.

2.7 Perceptions of emergency care in Kenyan communities lacking access to formalised emergency medical systems

Socioeconomic and cultural factors play a major role both in seeking and reaching emergency care. Community members in Kenya experience a wide range of medical emergencies, and seem to understand their time-critical nature. Access to emergency care in Kenya can be improved by encouraging recognition and initial treatment of emergent illness in the community, strengthening the pre-hospital care system, improving emergency care delivery at health facilities and creating new policies at a national level. These community-generated solutions likely have a wider applicability in the region.
2.8 Physician perceptions and recommendations about pre-hospital emergency medical services for STEMI in Abu Dhabi

Most physicians involved in STEMI care in Abu Dhabi are very likely to advise patients to use EMS for a cardiac emergency, but less likely to do so for themselves or their families. Different specialties had concordant opinions regarding steps to improve pre-hospital EMS care for STEMI.

2.9 Applying the lessons of maternal mortality reduction to global emergency health

Maternal health has been a major focus of the international community and this has resulted in a substantial decrease in maternal mortality globally. There has been less focus on global efforts to improve comprehensive emergency systems though. The specific application of the concepts used in the effort to decrease maternal mortality could lead to major improvements in global emergency health services. Adaptation of evaluation frameworks to include emergency sentinel conditions could allow effective monitoring of emergency facilities and further policy development.

2.10 Emergency care delivery recommendations for healthcare facilities in sub-Saharan Africa

A major barrier to successful integration of acute care into health systems is the lack of consensus on the essential components of emergency care within resource limited environments. The 2013 African Federation of Emergency Medicine Consensus Conference identified the essential services provision associated with 6 emergency sentinel conditions. Levels of emergency care were
assigned based on the expected capacity of the facility to perform signal functions, and the necessary human, equipment and infrastructure resources identified. These consensus-based recommendations provide the foundation for objective facility capacity assessment in developing emergency health systems that can bolster strategic planning as well as facilitate monitoring and evaluation of service delivery.

2.11 A reference standard for assessing paediatric triage scales in resource poor settings

In a two-round consensus building Delphi process a panel of emergency centre experts were asked to independently triage 50 clinical vignettes using one of four acuity levels. The vignettes were based on real paediatric EC cases in South Africa. Vignettes that reached a minimum of 80% group consensus for acuity ratings on either round one or two were included in the final set of reference vignettes. This study demonstrates how context-specific reference vignettes can be developed to provide a cheap, effective, and feasible means by which to evaluate paediatric triage systems in LMICs.

2.12 Investigation and management of foreign body ingestion in children

Foreign body ingestion in children is a common presentation to emergency centres. In South Africa, there are no established management guidelines. The study was a retrospective chart review of foreign body ingestion at a paediatric trauma centre, their presenting symptoms, investigations and subsequent management. It highlighted the need for the establishment of guidelines for the management of FB ingestion including hand held metal detectors (aimed at decreasing radiation exposure in this vulnerable population).
2.13 Tailoring training for paramedic-delivered CPR

Paramedics who received CPR training with a tailored programme were rated competent 70.9% of the time, compared with paramedics who attended the traditional programme and who achieved this rating 7.9% of the time. Specific improvements were seen in the time required to detect cardiac arrest, chest compression quality, and time to first monitored rhythm and delivered shock.

2.14 Chest ultrasound for military tuberculosis

Miliary tuberculosis is characterized by a multitude of small nodular opacities on chest radiography. Despite ultrasound of the chest gaining wider acceptance as a diagnostic tool of lung infections, sonographic changes of pulmonary miliary TB have not yet been reported. B-lines and comet-tail artefacts disseminated throughout multiple lung areas and a pattern of sub-pleural granularity as consistent changes seen in lung ultrasound of ten patients with pulmonary miliary TB diagnosed by chest radiography are described.

2.15 Huge variability in the availability of alternative devices for the management of the difficult airway

The study demonstrated that Western Cape public emergency centres are currently inadequately stocked with regard to alternative airway devices. Three centres (20%) had no alternative airway device; five centres (33.3%) stocked only one device; three centres (20%) had two devices and four centres (26.7%) had more than two devices. A guideline regarding the procurement and implementation of these devices is needed.
2.16 The Nigerian Building Collapse experience

2.17 Patient satisfaction with emergency departments

In NSH, found that orange, yellow and green priority patients spend an average 295, 286 and 451 minutes respectively in the EC. Despite their 451 minute total time, Green patients needed an average of 24 minutes of clinician time. Fast tracking in ECs would help alleviate much of the Green patient “burden” on these units.

2.18 Experiences and coping mechanism of EMS personnel to trauma

Qualitative work showed that EMS personnel face many traumatic experiences in their daily jobs, and that injured children are the most traumatic events. Staff experience avoidance symptoms and have no structured coping mechanisms. Very little or no training has been received to prepare them for the emotional effects. Integrated intervention programmes are needed.

2.19 Developing emergency medical dispatch systems in Africa

Emergency medical dispatch (EMD) systems are a crucial component of effective Emergency Medical Services (EMS) systems. They provide a means of public access to emergency care information and out-of-hospital emergency care resources and expertise. EMD systems also link various components of EMS, thereby improving efficiency and performance. As EMS systems are rapidly developing across many parts of Africa, EMD systems which are context appropriate are in great need, but are mostly absent despite the wide availability of telecommunications technology.

To facilitate the development of EMD systems appropriate for the African setting, the African Federation for Emergency Medicine (AFEM) and the International Academies of Emergency Dispatch (IAED) convened a working group in November 2014 to provide conceptual, technical, and innovative recommendations for contextually appropriate EMD systems for African settings. It is hoped that these recommendations will augment efficiency, effectiveness, and standardisation within and among African EMD systems, thereby improving health outcomes for sufferers of acute illness or injury.

2.20 Emergency care in 59 low-and middle-income countries: a systematic review

Emergency facilities in LMICs serve a large, young patient population with high levels of critical illnesses and mortality. This suggests that emergency care should be a global health priority. The cost–benefit ratio for improvements in emergency care is likely to be highly favourable, given the high volume of patients for whom high-quality care could be the difference between life and death. There are likely to be substantial opportunities to improve care and impact outcomes, in ways that could be rigorously evaluated with manageable sample sizes.

2.21 Electronic Medical Records

There is a growing need and tremendous push towards electronic medical records (EMRs) even in developing areas. This study sought to learn from the implementation process at one hospital in South Africa. In this hospital, EMRs were limited by paper charts needing to be scanned into a system, with limited record clerk and scanning equipment available. This resulted in a backlog of missing records. Future implementations of EMRs should strive for a fully electronic EMR that does not depend on scanning of paper records, and the upfront costs are expected to save the hospitals tremendously in the future.

2.22 Burn services in the Western Cape, South Africa

The incidence of burns was highest in the winter months, more than half of those affected were children, and the majority of burns were scalds from hot liquids. Most burn injuries managed at primary level were minor, with 75% of patients treated by nurse practitioners and discharged. The four regional secondary hospitals managed the majority of moderate to severe burns. There is room for improvement in terms of treatment facilities and consumables at all levels, regional hospitals being particularly restricted in terms of outdated equipment, a shortage of intensive care unit beds, and difficulties in transferring patients with major burns to a burns unit when indicated. The community management of paediatric burns was satisfactory, although considerable delays in transfer and insufficient pain control hampered appropriate care. A great need for ongoing education at all levels was identified. Ten strategies are presented that could, if implemented, lead to tangible improvements in the management of burn patients at primary and secondary levels in the Western Cape.

2.23 More ambulances is not the answer to improve key performance

A simulation model was created, based on input data from part of the EMS operations. Two different versions of the model were used, one with primary response vehicles and ambulances and one with only ambulances. In both cases the models were run in seven different scenarios. The first scenario used the actual number of emergency vehicles in the real system, and in each subsequent scenario vehicle numbers were increased by adding the baseline number to the cumulative total. The model using only ambulances had shorter response times and a greater number of responses meeting national response time targets than models using primary response vehicles and ambulances. In both cases an improvement in response times and the number of responses meeting national response time targets was observed with the first incremental addition of vehicles. After this the improvements rapidly diminished and eventually became negligible with each successive increase in vehicle numbers. The national response time target for urban areas was never met, even with a seven-fold increase in vehicle numbers.

2.24 The effect of the emergency medical services vehicle location and response strategy on response times

Response time is currently considered to be an important performance indicator in Emergency Medical Services (EMS) systems. A number of factors may affect response times, including the location of emergency vehicles and the type of response system design used. This study aimed to assess the effects of emergency vehicle location and response system design on response time performance in a model of a large South African urban EMS system, using discrete-event simulation. Results indicated that both the emergency vehicle location and response system design factors had a significant effect on response time performance, with more decentralised vehicle location having a greater effect.

2.25 Emergency care research priorities in South Africa

Using expert consensus, Barnetson defined research priorities which the 2 Divisions in Cape Town now use to drive their research areas. The expert group were primarily working in the Public Sector and so the results are appropriate for our context.

2.26 Major incidents in the Western Cape Province, South Africa

Most major incidents occurred in the City of Cape Town, but the Central Karoo district had the highest incidence. Transport-related incidents occurred most frequently; minibus taxis were involved in 312 major incidents. There was no significant difference between times of day when incidents occurred. Major incidents occurred more often than would have been expected compared with other countries, with road traffic crashes the biggest contributor. A national database will provide a better perspective of the burden of major incidents.

3 Research outputs: dissertations

3.1 Community-based perceptions of emergency care in communities lacking formalised emergency medicine systems

From: Broccoli M. Community-based perceptions of emergency care in communities lacking formalised emergency medicine systems. MSc thesis. University of Cape Town; 2015 (see publications for summary)

3.2 Poor knowledge amongst all levels of emergency care providers regarding child abuse

From: Dessena B. A study to determine perceived and actual knowledge of Cape Town Emergency Care Providers with regard to child abuse. MSc thesis. University of Cape Town; 2015
This study looked at the actual and perceived knowledge of Cape Town emergency Medical Care Providers in dealing with child abuse. It highlights that treatment of child abuse is mainly confined to treating of physical injuries at all levels of care and not dealing with disclosure of abuse. Responses across all 120 respondents revealed a huge gap in the training of this area.
3.3 Lack of first aid and basic life support skills in early childhood development workers and educators

From: Evans D. Evaluating the need for first aid and basic life support training in early childhood development workers and educators in Cape Town, South Africa. MMed thesis. University of Cape Town; 2015

The BLS and first aid knowledge of 214 ECD practitioners working in the Western Cape was evaluated in this study. The predefined pass mark of 75% was only achieved by 12.1% of the participants. The majority of participants reported that emergency incidents had taken place in their environment. 99% of the participants indicated a desire to pursue further education and training in first aid and BLS and all acknowledged the importance of training. There is a pressing need to train and educate staff regarding first aid and BLS practices.

3.4 Poor adherence to mental health act when dealing with the patient with a suicide attempt refusing care

A vignette-based survey was used to collect data related to training and knowledge of the mental health act in the prehospital environment. Key findings included negative attitudes towards suicidal patients, lack of use of formal suicide evaluation tools and finding suicidal patients dead on later return. Only 7% had specific training in the mental health act whilst 80% had no training in the management of suicidal patients. This did not correlate with qualification level. It is essential that training be addressed to promote a better understanding of care requirements in this vulnerable group.

3.5 Paediatric critical care pathways in the Western Cape

The Pathways to Care Project examined the journey through the health system of a cohort of critically ill children through expert review of each step from first access to healthcare through admission to Red Cross PICU or death in EC. Of 282 children, 85% were medical and 15% trauma. Global quality of care was graded poor in 20% and 50% had at least 1 major impact modifiable factor. Key modifiable factors related to access and identification of the critically ill, assessment of severity, inadequate resuscitation, delays in decision making and referral, and access to PICU. Standards compliance increased with increasing level of facility, as did caregiver satisfaction. Children (median age 7.8 months) presented primarily to PHC (54%), largely after hours (65%), and were transferred with median time from first presentation to PICU admission of 12.3 hours. There was potentially avoidable severity of illness in 74% of children, indicating room for improvement. More effective and objective ways of identifying and fast tracking acutely ill children are needed (especially in PHC). Common diagnoses such as respiratory tract infections were inadequately managed, particularly in infants, suggesting educational interventions could be focused on a small group of conditions. Rationalization (such as fast tracking of patients directly from PHC to PICU) and better prioritization of EMS services could improve referral delays, and review of the overall process and the system at the referral hospital would optimize scarce PICU resources. Many of the findings will almost certainly be generalizable to other sick children, and to adults too, although this was not explicitly investigated.

3.6 The role of online resources and social media in formal educational activities within Emergency Medicine Cape Town

From: Kleynhans AC. The utilisation of educational resources within the Divisions of Emergency Medicine at Stellenbosch University and the University of Cape Town. MMed thesis. Stellenbosch University. 2015

The thesis describes the usage of various educational resources by members of the Divisions of Emergency Medicine at Stellenbosch University and the University of Cape Town. Only 47% and 25% of division members, respectively, utilize Facebook and Twitter daily as an educational resource. The top international Emergency Medicine and Critical Care blogs are frequently being used (71%). YouTube (35%) and podcasts (21%) were the most commonly utilized multimedia resources. The majority (94.6%) still make use of textbooks. Smartphones and tablets are the
primary means of accessing electronic resources, a trend explained in part by general availability, convenience and ease of use. An opportunity exists for greater integration of online resources and social media in formal educational activities to enhance multimodal and self-directed learning. Specific training in the use of these resources, as well as how to appraise them, may further improve their utility.

3.7 Risk adjusted mortality rates, hospital standardised mortality ratio and APACHE IV

From: Toua RE. Risk adjusted mortality rates: Do they differ if based on administrative data (hospital standardised mortality ratio) versus a physiological predictive model (APACHE IV ®)? MPhil thesis. University of Cape Town; 2015

Predicted mortality as calculated with the Hospital Standardised Mortality Ratio was compared to a physiological model (APACHE ®IV) and stratified by prediction level (<10% predicted mortality, 10-50% predicted mortality or >50% predicted mortality). The administrative predictive model correlate well at equal or less to 50% predicted mortality rate, while not showing a correlation at high predicted mortality rates (>50%) and is not suitable for predicting mortality in the highest stratum.

3.8 Knowledge and skills of Basic Life Support CPR by EMS

From: Veronese JP. An Assessment of theoretical knowledge and psychomotor skills of Basic Life Support Cardio-pulmonary Resuscitation provision by Emergency Medical Services in a province in South Africa. MSc thesis. University of Cape Town; 2015

Both the skills and theoretical knowledge of BLS CPR were assessed in EMS providers in the Eastern Cape. Median knowledge score was 50% and median skills 22%. Continuous and tailored BLS CPR instruction is required to bring EMS up to international competency standards. The findings raise a concern for BLS CPR skill and knowledge of EMS providers in other provinces including the Western Cape. It is recommended that quality checks on skill and knowledge of BLS CPR be initiated.
4 Opinion pieces

4.2 De Vries S, Geduld H. Geography should be taught at medical school. S Afr Med J. 2015;105(10):816
